

Our film uses realistic AI-generated imagery to raise awareness of urban heat. This creates a risk that viewers could mistake fictional scenes for footage of a real place or heatwave. We reduced this risk by avoiding named locations and specific temperature claims in the film. The characters are fictional and were not intentionally based on real people. However, we still need to add a visible “AI-generated fictional scenes” label so viewers understand what they are watching. We also recognise that dry leaves do not prove climate change, and that finding shade does not solve the wider problem of urban heat. Our story illustrates one benefit of greener public spaces without measuring its effect. Generating the film required repeated attempts, which consumed computing resources; one render took approximately an hour. We did not measure electricity use, so we cannot claim that production had a low environmental impact. We reused accepted starting images, but should also record the total number of generations and avoid unnecessary rerenders. The intended educational value must be weighed against these costs, and we have not yet tested whether the film improves viewers’ understanding.
